## **Abstract**

Cooperative manipulation with human guidance can be used to solve versatile tasks. A new approach to system modelling and control in cooperative manipulation is the use of port-Hamiltonian systems. Starting from modelling of a cooperative manipulation set-up a model-based controller in the framework of Intrinsically Passive Control is derived. In contrast to the quasi-static implementations for robot hands, the controller has fully dynamic impedance relations. The good dynamic performance of the proposed control scheme is shown by simulation and compared to simulations of state-of-the-art controllers in cooperative manipulation.

# Chapter 1

## Introduction

Cooperative manipulation involves two or more robot arms cooperatively moving or manipulating a common object [CM08]. Such a set-up overcomes many limitations seen by single robots. The prime example is the transportation of a large or heavy object, where a single manipulator would exert large local wrenches on the object. Back in the 1940s two remote manipulators were used to handle radioactive goods [Goe52]. Around 1990 the *NASA* researched cooperative manipulation in space construction applications [SC92]. Specifically in [LS05] a cooperative manipulation strategy for the repair of the Hubble Space Telescope is proposed. Other tasks of cooperative manipulation are for example:

- assembly of multiple parts without using special fixtures
- grasping an object without rigid fixture but by exerting a suitable squeezing force
- deforming a flexible object
- coordinated use of tools

A recent application has been presented at the Fukushima Daiichi Nuclear Power Station. By equipping a two-armed robot with different tools the robot is capable of grasping an item (e.g. piping) and cutting it with the other, see Fig. 1.1. For sensitive tools like an angle grinder it is favourable that movement and contact forces of both arms are coordinated.

Space and hazardous environments are fruitful environments for cooperative manipulators. Often they are controlled by a human operator from a safe location. Combining human reasoning and the enhanced flexibility of a cooperative set-up is a powerful combination in an unstructured environment. A human in the control loop comes with superior foresight and planning capabilities. To fully exploit this additional flexibility we require control architectures able to perform all the aforementioned tasks and operable in a comfortable and efficient manner.

Figure 1.1: Demonstration of the tele-operated MHI MEISTeR robot at Fukushima Daiichi Nuclear Power Station [LTD14]

To address the first requirement the controller realizes changes of formation and re-locates the constrained system. A change of formation first of all means the opening and closing of a grasp around a common object. A virtual object and variable rest-length springs are introduced, the springs couple the virtual and the actual object. The size of virtual object specifies the rest-lengths, by choosing it smaller than the actual a grasping force is exerted. By choosing it bigger the grasp is opened and the actual object is released. Changing of rest-lengths means to change the potential energy stored in the springs. Since the controller itself is passive, the energy is exchanged with a distinct power port. In order to relocate the formation a spring is connected from the virtual object center to the desired new position/orientation. This ensures compliant behavior between (virtual) object and environment. Note that this concept is called *Intrinsically Passive Controller* (IPC) and was introduced by Stramigioli [Str01b], the control architecture described in the main part will closely stick to this concept.

The controller provides a reasonable layer of abstraction and takes responsibilities from the operator, in order to not overstrain her/his attention and let him focus on important elements of the task. To ensure a secure and stable grasp, the formation of robots is locally controlled without the help of the human. For dynamic manipulation tasks grasp force optimization can be utilized to limit internal to the absolute minimum. The control system provides appropriate feedback to provide better perception on the work environment and to make the job more intuitive. The user

specifies system motion and is provided with information about the necessary forces to accomplish the commanded motion. Thereby s/he gets a natural intuition of how much work has been done by the robots. To this end the controller shall never be a source of additional energy, the only way energy is fed into the system is by request of the operator, i.e. the controlled robots are passive. The maximum extractable energy is always bounded, the operator can estimate the stored energy and possible effects when interacting with the environment. Passive robotic systems are always stable when interconnected passive environments/humans and can be stable with some active systems. On the contrary, if the controlled robot is not passive, there is always a passive environment that destabilizes the interconnected system [Str15].

## 1.1 Problem Statement

Manipulating an unknown object in an unstructured environment is an interesting task for a human-guided cooperative manipulation set-up. Dropping the assumption of a rigid- connection between manipulator and object, the grasp has to be actively stabilized under varying circumstances. During dynamic manipulation a slipping of contact due to the inertia of the object has to be avoided using an automatic mechanism. On the other hand the operator must directly adjust grasp forces for heavy or fragile objects.

Position and velocity of the manipulated object are difficult to track in an everyday setting. Usually only end-effector position and velocity of the robots are available. Object position has to be estimated from the known data.

For grasping an object of unknown or even flexible shape, the determination of a fixed grasp map in advance is not useful. Size and shape of the grasp have to be determined by the operator during the grasp process. The controller has to be flexible to varying grasp geometries during the whole task execution.

Integrating the human into the control loop, energetic passivity of the closed loop system is a meaningful and intuitive way to ensure stability and a natural way of interaction. Energetic passivity limits the extractable mechanical energy from the closed loop system. This means that the potential damage is also limited. Energetic passivity of the robotic system ensures stability of the interconnection stability with any passive systems. Since humans and many relevant environments are passive the closed loop system will always be stable if the overall control scheme is designed energetically passive.

## 1.2 Related Work

A notable class of control architectures for cooperative manipulation is hybrid position/force control, with a motion control loop for trajectory tracking and a force control loop for internal forces [WKD92, Hsu93]. Their drawback is the inability to handle non-contact to contact transitions. Hogan introduced impedance control,

which enforces a relation between force and motion [Hog84]. Its first application in cooperative manipulation was in [SC92] for realizing compliant object-environment interaction (external impedance control). Bonitz and Hsia [BH96] applied the concept to the manipulator-object relation (internal impedance control).

More recent impedance control schemes can be classified in terms of the information and sensor data available for the problem. Frugal architectures are formation control [SMH15] and the static IPC [WOH06]. Both do not incorporate the object dynamics in control, thus very little knowledge about the object (e.g. dimensions) is necessary. The control loops depend only on relative positions and velocities of the manipulators and do not require object tracking. Neglecting considerable object dynamics is an obvious drawback of the schemes.

The concept of the *Intrinsically Passive Controller* (IPC), introduced by Stramigioli [Str01b] and called dynamic IPC by Wimböck et al. [WOH08], tries to overcome some of the limitations. In the controller the object is represented by a virtual pendent and simulated to reproduce its dynamics for control purpose. This has the advantage that still no tracking of the object is required, object velocity and even acceleration can be obtained from the simulation.

Techniques which rely on exact knowledge of the object motion were introduced by Caccavale et al. [CV01, CCMV08] and more recent [HKDN13] and [DPEZ<sup>+</sup>15]. It is common to them that they assume rigid fixtures to a rigid object, these conditions overcome the problem of object tracking. The approaches by Caccavale and co-workers use force/torque sensors at the manipulators to establish compliant object environment interaction, for this purpose Heck et al. [HKDN13] assume to have an exact model of the environment. Stramigioli's IPC implements a compliant relation between virtual object and environment.

The human operator must be able control the manipulators at a reasonable degree of complexity, therefore in an direct master-slave approach each robot is controlled independently by a human operator. Exactly coordinating their motions is a difficult task for humans, as a consequence a certain amount of autonomy is left to the robot system, enabling a single operator to control the cooperative system. Lee and Spong [LS05] apply the master-slave scheme but treat the constrained system as a single slave, while the formation is preserved by the robots autonomously. Many master-slave systems give the operator force-feedback, while s/he commands the motion. This helps the operator compensate for resistances and gives a natural feeling of the interaction with the environment. The structure then is fully bi-directional, ones refers to bilateral telemanipulation [NPH08]. Leader-follower [SMH15, SMP14] schemes differ in terms of feedback provided to the operator. Tactile and visual types are non-reactive, i.e. they do not induce operator movements reacting to a back-driving force [MT93]. A purely vision-based architecture is introduced by Gioioso et al. [GFS<sup>+</sup>14], hand gestures are used to both control the motion of the constrained system and the opening and closing of a grasp. Control architectures that leave even further autonomy to the robot system and possess a closed local, autonomous control loop, are categorized as supervisory control. They interacts with the opera-

tor by continuously sending information about the state and periodically receiving commands [She92].

The assumption of rigid fixtures between manipulators and object is very common in cooperative manipulation, Lee and Spong [LS05] are an exception. Friction grasps are mainly researched in robot hand literature ([WOH06, WOH08, Str01b]). For the stabilization of a friction grasp it is vital to choose appropriate forces depending on the dynamic state. Therefore the Coulomb friction constraints along with other criteria (safety margins, force limits) can be formulated as a cost function for optimization. Buss et al. [BHM96] realized that the Coulomb friction constraints can be formulated as positive definite matrices, Han et al. [HTL00] gave a linear matrix inequality problem. For this type of optimization problems very efficient, real-time solvers exist.

## Chapter 2

# port-Hamiltonian system modelling

In this chapter a modelling approach of interactive mechanical systems based on the port-Hamiltonian framework is introduced. Port based modelling aims at providing a consistent system description over different physical domains. In the presented case we stick to the mechanical domain, with two energies types of interest: kinetic and potential energy. Modelling is done by dividing the system in simple Hamiltonian subsystems and interconnecting them using methods of network theory.

Kinematic constraints limit the possible motion of the system's sub-members and impose a set of differential-algebraic equations (DAE). The DAE description is reformulated into an input-output representation, which is beneficial when it comes to control.

### 2.1 Hamiltonian description of mechanical systems

The Hamiltonian equations of motion are related to the better known Euler-Lagrange equations with the Legendre transformation. Both are formulations on energy level thus they are useful for a continuous description of mixed-energy systems, e.g. a pendulum alternating between kinetic and potential energy periodically. The classical Hamiltonian equations for a mechanical system are:

$$\begin{aligned}\dot{q} &= \frac{\partial H}{\partial p}(q, p) \\ \dot{p} &= -\frac{\partial H}{\partial q}(q, p) + F\end{aligned}\tag{2.1}$$

Where Hamiltonian  $H(q, p)$  is the total energy of the system,  $q = (q_1, \dots, q_k)^T$  denotes the generalized coordinates of the system with  $k$ -degrees of freedom and  $p = (p_1, \dots, p_k)^T$  is the vector of the generalized momenta.  $F$  is the input of generalized forces.

An important aspect of PHS is conservation of energy, i.e. supplied work is stored in the system [vdS06]. The energy balance of the system is:

$$\frac{d}{dt}H = \frac{\partial^T H}{\partial q}(q, p)\dot{q} + \frac{\partial^T H}{\partial p}(q, p)\dot{p} = \frac{\partial^T H}{\partial p}(q, p)F = \dot{q}^T F \quad (2.2)$$

Note that the product of generalized force and velocity is mechanical power. Depending on the energy type of the mechanical system (kinetic or potential), the input is either or force or velocity and the output being velocity or force respectively. This motivates the more general concept of flows  $f$  and efforts  $e$ , being the input and output of a pHS.

$$\begin{aligned} \dot{q} &= \frac{\partial H}{\partial p}(q, p) \\ \dot{p} &= -\frac{\partial H}{\partial q}(q, p) + g(q)f \\ e &= g^T(q)\frac{\partial H}{\partial p}(q, p) \end{aligned} \quad (2.3)$$

**Example:** Consider a simple one-dimensional spring-mass system described by  $m\ddot{x} = -kx + F_e$ . Where  $m, k, F$  denote the mass, stiffness and external force acting on the mass. We can give a state space formulation for the system

$$\begin{pmatrix} \dot{x} \\ \ddot{x} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -\frac{k}{m} & 0 \end{pmatrix} \begin{pmatrix} x \\ \dot{x} \end{pmatrix} + \begin{pmatrix} 0 \\ 1 \end{pmatrix} \frac{F_e}{m} \quad (2.4)$$

In the Hamiltonian approach the system is described based on the Hamiltonian energy functions, being  $V_s = \frac{1}{2}kq^2$  for the spring and  $V_m = \frac{1}{2m}p^2$  for the mass. The state variables are thus replaced by the energy states, the *configuration*  $q = x$  accounting for the spring and the *momentum*  $p = m\dot{x}$  accounting for the mass.

$$\begin{aligned} \begin{pmatrix} \dot{q} \\ \dot{p} \end{pmatrix} &= \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} \frac{\partial V}{\partial q}(q, p) \\ \frac{\partial V}{\partial p}(q, p) \end{pmatrix} + \begin{pmatrix} 0 \\ 1 \end{pmatrix} F_e \\ e &= (0 \quad 1) \begin{pmatrix} \frac{\partial V}{\partial q}(q, p) \\ \frac{\partial V}{\partial p}(q, p) \end{pmatrix}, \quad V = V_s + V_m \end{aligned} \quad (2.5)$$

Key aspect of pHS is the division into atomic energy storing elements (spring, mass) and their proper interconnection. In the example we have implicitly done this by defining energy functions and states for both elements. The rules of interconnection are explicitly given by :

- equal velocity of spring tip and mass  $\dot{x} = \frac{\partial V}{\partial p}$  (rigid connection)
- opposite forces at spring tip and mass  $\dot{p} = -\frac{\partial V}{\partial q} + F_e$  (principle of action-reaction)

Table 2.1: PHS variables of mechanical elements

	<b>Spring</b>	<b>Mass</b>	<b>Damper</b>
<b>Effort variable</b>	Force $F$	Velocity $\dot{x}$	Force $F$
<b>Flow variable</b>	Velocity $\dot{x}$	Force $F = \dot{p}$	Velocity $\dot{x}$
<b>State variable</b>	Position $x$	Momentum $p$	-
<b>Energy function</b>	$E(x) = \frac{1}{2}kx^2$	$E(p) = \frac{p^2}{2m}$	$E(\dot{x}) = D\dot{x}^2$ (diss. co-energy)

Due to the *second law of thermodynamics* real mechanical systems are never energy conservative. Thus we require energy dissipating elements (since thermal energy is "lost" w.r.t. the mechanical domain). A mechanical system is thus described by its basic elements: springs, masses and dampers. Table 2.1 gives an overview of the elements and their characterizing quantities. Note that dissipation elements do not have a state because they are static. It is worth pointing out that the *flows* are the time derivatives of the *states*.

Next to *energy-storing* and *-dissipating* there is a third class of elements, namely *energy-conservative* structures. Elements within this group are transformers, gyrators and ideal constraints, they are used to redirect the power flow in the system. It is possible to merge all *energy-storing* elements into a single object representation (see Fig. 2.1). Analogously this can be done for the dissipation elements. The interconnecting structure (denoted by  $\mathcal{D}$  in Fig. 2.1), consisting of the *energy-conservative* elements, formalizes the energy routing and geometric dependencies of the system. A detailed explanation is given in the next subsection.

Figure 2.1: port-Hamiltonian system structure [vdS06]

Complex physical systems can be modelled as a network of energy storing and dissipating elements, similar to representation of electrical networks consisting of resistors, inductors and capacitors. The rules of interconnection are Newton's third law (action-reaction), Kirchhoff's laws and power-conserving elements like transformers or gyrators. The aim of PHS-modelling is to describe the power-conserving elements with the interconnection laws as a geometric structure and to define the Hamiltonian function as the total energy of the system.

The power flowing between the system's portions is described by the flow-effort product  $e^T f$ . A pair  $(f, e)$  is called a *port*. The external port  $f_P, e_P$  describes the energy flow to/from environment or a controller.

### 2.1.1 Dirac structures and interconnection ports

The energy-routing structure forms the basis of every pHs. It can be compared to the printed circuit board in electronics, while capacitors, inductors and resistors being the energy-storing and damping elements. Mathematically it has the form of a *Dirac* structure. The main property of a Dirac structure is power conservation, i.e. the power flowing into and out of it always sums to zero. We can define the set of ports  $(f, e)$  connecting to the Dirac structure  $\mathcal{D}$ , thus

$$e^T f = 0 \quad \forall (f, e) \in \mathcal{D} \quad (2.6)$$

Where  $\mathcal{D}$  is a subspace of the space of flow and effort  $\mathcal{D} \subset \mathcal{E} \times \mathcal{F}$ . The space of flows is  $f \in \mathcal{F}$  the space of efforts is its dual linear space  $e \in \mathcal{E} = \mathcal{F}^*$ . The Dirac structure has the same dimension than the space of flow  $\dim \mathcal{D} = \dim \mathcal{F}$ . Further mathematical requirements can be found in literature [vdS06, ?]. The interconnection of ports is defined by the Dirac structure matrix  $D$

$$\begin{pmatrix} e_P \\ f_S \\ e_R \end{pmatrix} = D \begin{pmatrix} f_P \\ e_S \\ e_R \end{pmatrix} \quad (2.7)$$

with the internal elements

$$D := \begin{pmatrix} D_P & G_1 & G_2 \\ -G_1^T & D_S & G_3 \\ -G_2^T & -G_3^T & D_R \end{pmatrix} \quad (2.8)$$

and  $D_P, D_S, D_R$  are skew-symmetric. Thus  $D = -D^T$  is skew-symmetric, this is necessary for  $e^T f = 0$ . The power exchanged through a port is given by  $e_*^T f_*$ . In Fig. 2.1 the port variables entering the Dirac structure have already been split.

#### Energy storage port

The port accounts for the internal storage of the system, its port variables are  $(f_S, e_S)$ . The power supplied through this port is stored in the Hamiltonian energy function  $V(x)$  of the system. Here  $x$  denotes a general energy state variable. The resulting energy balance is:

$$\frac{d}{dt} H = \frac{\partial^T V}{\partial x}(x) \dot{x} \quad (2.9)$$

The flow variable is the energy rate  $f_S = -\dot{x}$  and the effort variable is  $e_S = \frac{\partial H}{\partial x}(x)$ .

#### Energy dissipation port

The port corresponds to internal dissipation and can be used to model resistive elements. The port variables are described by the general resistive relation

$$F(f_R, e_R) = 0 \quad (2.10)$$

with the property  $e_R^T f_R \leq 0$  (energy dissipation). An important special case is the input-output resistive relation  $f_R = -F(e_R)$ , for linear elements simply

$$f_R = -R e_R, \quad R = R^T \geq 0 \quad (2.11)$$

For an uncontrolled system that does not interact with the environment, i.e. no energy exchange through the external port, the energy balance is:

$$\frac{dH}{dt} = -e_S^T f_S = e_R^T f_R \leq 0 \quad (2.12)$$

### External port

The external port  $(f_P, e_P)$  can be further split into an environment *interaction*  $(f_I, e_I)$  and a *control* port  $(f_C, e_C)$ , satisfying  $e_P^T f_P = e_I^T f_I + e_C^T f_C$ . The power balance of the whole system then is

$$e_S^T f_S + e_R^T f_R + e_I^T f_I + e_C^T f_C = 0 \quad (2.13)$$

or by using (2.9)

$$\frac{dH}{dt} = e_R^T f_R + e_I^T f_I + e_C^T f_C \quad (2.14)$$

### Interconnection of port-Hamiltonian systems

It is important to notice that the interconnection of two pHs is again a pHs [?]. Consider two general pHs ( $i = 1, 2$ ) with open control and environment interaction ports:

$$\dot{x}_i = (J_i - R_i) \frac{\partial H_i}{\partial x_i} + (g_i^C \quad g_i^I) \begin{pmatrix} f_i^C \\ f_i^I \end{pmatrix} \quad (2.15)$$

$$\begin{pmatrix} e_i^C \\ e_i^I \end{pmatrix} = \begin{pmatrix} (g_i^C)^T \\ (g_i^I)^T \end{pmatrix} \frac{\partial H_i}{\partial x_i} \quad (2.16)$$

Where  $J_i, R_i$  are a skew-symmetric structure matrix and a positive-semi-definite symmetric dissipation matrix.  $(g_i^C \quad g_i^I)$  is a general input matrix. For notational convenience the usual dependencies on the states have been omitted. The control inputs and outputs are now connected by setting  $f_1^C = e_2^C$  and  $f_2^C = -e_1^C$ . Note that the minus sign is necessary for power conservation. The power exchanged by the  $i$ -th system is  $P_i = (e_i^C)^T f_i^C$ , therefore the total exchanged energy fulfils  $P_1 + P_2 = 0$ . The resulting interconnected system has still the environment interaction ports open:

$$\dot{x} = (J - R) \frac{\partial H}{\partial x} + (g_1^I \quad g_2^I) \begin{pmatrix} f_1^I \\ f_2^I \end{pmatrix} \quad (2.17)$$

$$\begin{pmatrix} e_1^I \\ e_2^I \end{pmatrix} = \begin{pmatrix} (g_1^I)^T \\ (g_2^I)^T \end{pmatrix} \frac{\partial H}{\partial x} \quad (2.18)$$

Where  $x = (x_1, x_2)^T$  and  $H = H_1 + H_2$  is the sum of the two energies. The structure and dissipation matrix become:

$$J = \begin{pmatrix} J_1 & g_1^C (g_2^C)^T \\ -g_1^C (g_2^C)^T & J_2 \end{pmatrix}$$

,

$$R = \begin{pmatrix} R_1 & 0 \\ 0 & R_2 \end{pmatrix}$$

## 2.2 3D-space modelling of mechanical systems

### 2.2.1 Euclidean space and motions

#### Coordinate frames

A coordinate frame of the three-dimensional Euclidean space is a 4-tuple of the form  $\Psi = (o, \hat{x}, \hat{y}, \hat{z})$ . Where  $o$  is the three-dimensional vector of the origin and  $\hat{x}, \hat{y}, \hat{z}$  are the linear independent, orthonormal coordinate vectors. Consider two coordinate frames  $\Psi_1, \Psi_2$  which share the same origin but differ in orientation due to different choices of  $\hat{x}_i, \hat{y}_i, \hat{z}_i$ ,  $i = 1, 2$ . The change of orientation from  $\Psi_i$  to  $\Psi_j$  is described by the rotation matrix  $R_i^j$ . The set of rotation matrices is called *special orthonormal* group ( $SO(3)$ ) [Str01a] and is defined as:

$$SO(3) = \{R \in \mathbb{R}^{3 \times 3} \mid R^{-1} = R^T, \det R = 1\} \quad (2.19)$$

Usually coordinate frames are defined with respect to an inertial frame, and the coordinate vectors  $\hat{x}, \hat{y}, \hat{z}$  are chosen equal for all frames, deviations of orientation are represented by a rotation matrix relative to the inertial frame. In general a change of coordinate frames from  $\Psi_i$  to  $\Psi_j$  can be expressed with the homogeneous matrix

$$H_i^j := \begin{pmatrix} R_i^j & p_i^j \\ 0_{1 \times 3} & 1 \end{pmatrix}$$

Where  $p_i^j = o_j - o_i$  denotes the changes of origins. A point  $p^1 \in \mathbb{R}^3$  expressed in  $\Psi_i$  is cast into  $\Psi_j$  by

$$\begin{pmatrix} p^j \\ 1 \end{pmatrix} = H_i^j \begin{pmatrix} p^i \\ 1 \end{pmatrix} \quad (2.20)$$

. The inverse transformation  $H_j^i$  is given by

$$H_j^i = (H_i^j)^{-1} = \begin{pmatrix} (R_i^j)^T & -(R_i^j)^T p_i^j \\ 0_{1 \times 3} & 1 \end{pmatrix}$$

and is still a homogeneous matrix. The set of homogeneous matrices is called the *special Euclidean* group:

$$SE(3) := \left\{ \begin{pmatrix} R & p \\ 0 & 1 \end{pmatrix} \mid R \in SO(3), p \in \mathbb{R}^3 \right\} \quad (2.21)$$

The  $SE(3)$  is a matrix lie group, composed of the set of homogeneous matrices  $H_i^j$  and the matrix multiplication being the group operation. For more information on Lie groups see e.g. [Str01b].

### Twists and wrenches

Consider any point  $p$  not moving in coordinate frame  $\Psi_i$ , i.e.  $\dot{p}^i = 0$ . If  $p$  is moving in another coordinate frame  $\Psi_j$ , the two frame move with respect to each other. The trajectory can be described as a function of time:  $H_i^j(t) \in SE(3)$ . By differentiating (2.20) one obtains

$$\begin{pmatrix} \dot{p}^j(t) \\ 1 \end{pmatrix} = \dot{H}_i^j(t) \begin{pmatrix} p^i \\ 1 \end{pmatrix}$$

$\dot{H}_i^j$  describes both motion and a change of the reference frame. A separated representation is

$$\begin{pmatrix} \dot{p}^j(t) \\ 1 \end{pmatrix} = \tilde{T}_i^{j,j} \left( H_i^j \begin{pmatrix} p^i \\ 1 \end{pmatrix} \right) \quad (2.22)$$

More formally speaking  $\dot{H}_i^j$  is a tangential vector along the trajectory  $H_i^j(t)$  and thus in the tangent space of the  $SE(3)$ :  $\dot{H}_i^j \in T_{H_i^j}SE(3)$ . The tangent space  $T_{H_i^j}SE(3)$  depends on the relation of  $\Psi_i$  and  $\Psi_j$ . To obtain a representation of motion which is referenced to a coordinate frame, we can map  $\dot{H}_i^j$  to the identity of the  $SE(3)$ . At the identity  $e$  of the  $SE(3)$  the tangent space  $T_eSE(3)$  has the structure of a Lie algebra. The Lie algebra of the  $SE(3)$  is denoted by  $\mathfrak{se}(3)$ . This is done either by left or right translation, for a definition see [Str01b]. The right translation is used in (2.22) and is written compact

$$\dot{H}_i^j = \tilde{T}_i^{j,j} H_i^j \quad (2.23)$$

The left translation leads to

$$\dot{H}_i^j = H_i^j \tilde{T}_i^{i,j} \quad (2.24)$$

We call  $\tilde{T} \in T_eSE(3)$  a twist and the  $\mathfrak{se}(3)$  the space of twists. It can already be seen from the upper equations that different representations exist:

- $T_i^{k,j}$  is the twist of  $\Psi_i$  with respect to  $\Psi_j$  expressed in the frame  $\Psi_k$
- $T_i^j = T_i^{j,j}$  is the twist of  $\Psi_i$  with respect to  $\Psi_j$  expressed naturally in  $\Psi_j$

The  $4 \times 4$  matrix  $\tilde{T}$  can be decomposed and there exists also a vector representation  $T \in \mathbb{R}^6$

$$\tilde{T} = \begin{pmatrix} \tilde{\omega} & v \\ 0 & 0 \end{pmatrix}, \quad T = \begin{pmatrix} \omega \\ v \end{pmatrix}$$

Wherein  $v$  is the velocity and  $\omega$  is the angular velocity.  $\tilde{\omega}$  is the skew-symmetric representation of the vector  $\omega$

$$\omega = \begin{pmatrix} \omega_1 \\ \omega_2 \\ \omega_3 \end{pmatrix} \Rightarrow \tilde{\omega} = \begin{pmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & \omega_1 \\ -\omega_2 & \omega_1 & 0 \end{pmatrix} \quad (2.25)$$

Changes of coordinates for twists are of the form

$$\tilde{T}_i^{j,j} = \tilde{T}_i^j = H_i^j \tilde{T}_i^{i,j} H_j^i$$

or for the vector representation

$$T_i^j = Ad_{H_i^j} T_i^{i,j}, \quad Ad_{H_i^j} = \begin{pmatrix} R_i^j & 0 \\ \tilde{p}_i^j R_i^j & R_i^j \end{pmatrix}$$

The dual vector space of  $\mathfrak{se}(3)$  is the space of linear operations from  $\mathfrak{se}(3)$  to  $\mathbb{R}$ . It is denoted by  $\mathfrak{se}^*(3)$  and represents the space of wrenches  $W$ .

Wrenches decompose to moments  $m$  and forces  $f$ .

$$W = (m \ f), \quad \tilde{W} = \begin{pmatrix} \tilde{f} & m \\ 0 & 0 \end{pmatrix}$$

Again  $\tilde{W} \in \mathbb{R}^{4 \times 4}$  is a matrix while  $W \in \mathbb{R}^6$  is the row vector representation. The change of coordinates for twists is similar to the case of twists:

$$(W^i)^T = Ad_{H_i^j}^T (W^j)^T$$

Here the mapping is in the opposite direction, from  $\Psi_j$  to  $\Psi_i$ , what is a consequence of the fact that wrenches are duals to twists. Again there are different representations of wrenches:

- $W_i^{k,j}$  is the wrench applied to a spring connecting  $\Psi_i$  to  $\Psi_j$  on the side of  $\Psi_i$  expressed in the coordinate frame  $\Psi_k$ .
- $W_i^k$  is the wrench applied to a body attached to  $\Psi_i$  expressed in the coordinate frame  $\Psi_k$ .

Connecting a body and spring in the point  $\Psi_i$  and applying the principle of action and reaction we get  $W_i^{k,j} = -W_i^k$ . Due to the nodicity of a spring we have  $W_i^{k,j} = -W_j^{k,i}$

Recalling Subsection 2.1.1 the power flowing through a port is defined by the dual product of an effort and flow pair, which are from a vector space and its dual respectively. On a vector space level the power port  $\mathcal{P}$  is defined by the Cartesian product of the Lie algebra  $\mathfrak{se}(3)$  and its dual  $\mathfrak{se}^*(3)$ :  $\mathcal{P} = \mathfrak{se}(3) \times \mathfrak{se}^*(3)$ . The mechanical power exchanged at the port is simply  $P = WT$ .

## 2.2.2 Dynamics of physical components

### Springs

A *spring* is the ideal, lossless element storing potential energy. It is connected to two bodies and is defined by an energy function. The energy is a function of the

relative displacement of the attached bodies. Consider a spring between the two bodies  $B_i$  and  $B_j$ , with coordinate frames  $\Psi_i$  and  $\Psi_j$  fixed to the respective body. The stored potential energy is positive definite function of the form [SMA99]

$$V_{i,j} : SE(3) \rightarrow \mathbb{R}; H_i^j \mapsto V_{i,j}(H_i^j) \quad (2.26)$$

Recalling the general equations of a pHS and the assignment of the variables from Subsection 2.1 we already have the structure of the pHS equations for a spring. The state variable is the relative displacement  $H_i^j$ , the effort variable is the wrench  $W_i^{j,j}$  and the flow variable is the twist  $T_i^j$

$$\begin{aligned} \dot{H}_i^j &= T_i^j H_i^j \\ W_i^{j,j} &= \frac{\partial V_{i,j}}{\partial H_i^j} (H_i^j)^T \end{aligned} \quad (2.27)$$

Note that  $V_{i,j}$  is an energetic minimum when  $H_i^j$  is the identity matrix  $I_4$ . An energetic minimum is physically necessary, otherwise infinite energy would be extractable. With  $H_i^j = I_4$  the frames  $\Psi_i$  and  $\Psi_j$  coincide. It is possible to define springs with non-zero rest-length by introducing coordinate frames  $\Psi_{ic}$  and  $\Psi_{jc}$  rigidly attached to  $\Psi_i$  and  $\Psi_j$  respectively. The spring is now between the new frames, thus the energetic minimum is  $H_{ic}^{jc} = I_4$ . The displacements  $H_{ic}^{jc}, H_{jc}^{ic}$  are the resulting rest-lengths. Frames  $\Psi_{ic}$  and  $\Psi_{jc}$  can be chosen to represent the *center of stiffness*, where translation and rotation are maximally decoupled [SMA99].

### Variable rest-length springs

Varying the rest-lengths of springs in manipulator-object interaction allows to perform a grasp and specify grasping forces. The rest-length influences the energy configuration, to allow for controlled changes of rest-length an additional power port is introduced. The chosen hinge points  $\Psi_b, \Psi_j$  of the spring define an axis, known as the principal axes of stiffness. Changes of the rest-length leave this axis unaffected, i.e. the displacement is in-line. With reference to Fig. 2.2, the change of rest-length is a change of relative displacement of  $\Psi_b$  and  $\Psi_i$ :  $H_i^b$ . Towards a PHS

Figure 2.2: Variable rest-length spring [SMA99]

representation we need to identify the components contributing to the deformation

twist of the spring  $T_i^j$ : the displacement twist of the bodies attached to the spring  $T_b^j$  and the twist resulting from a commanded change of the rest-length  $T_i^b$  [SD01].

$$T_i^j = T_b^j + Ad_{H_b^j} T_i^b \quad (2.28)$$

Since no additional energy storages were introduced, the Hamiltonian function is equal to the case of the simple spring. We can write the two-port Hamiltonian system of a variable length spring as

$$\begin{aligned} \dot{H}_i^j &= \left( \begin{pmatrix} 1 & Ad_{H_b^j} \end{pmatrix} \begin{pmatrix} T_b^j \\ T_i^b \end{pmatrix} \right) H_i^j \\ \begin{pmatrix} W_b^{j,j} \\ W_i^{b,b} \end{pmatrix} &= \left( \begin{pmatrix} 1 \\ Ad_{H_b^j}^T \end{pmatrix} \frac{\partial V_{i,j}}{\partial H_i^j} \right) (H_i^j)^T \end{aligned} \quad (2.29)$$

### Inertias

The kinetic energy of a body is a function of its relative motion with respect to an inertial frame  $\Psi_0$ . The body's dynamic properties are described by the inertia matrix  $M_b$ , which consists of a mass and rotational inertia components. Consider the classical description of a body's dynamics:

$$M_b \dot{T}_b^{b,0} = C_b T_b^{b,0} + W_b^b \quad (2.30)$$

Where  $C_b$  accounts for Coriolis and centripetal terms and  $W_b^b$  is the external wrench acting on the body.

Recall from Table 2.1 that the energy state variable is the momentum  $P_b^b = M_b T_b^{b,0}$  and the flow variable is the wrench, we can reformulate the previous equation to PHS form

$$\begin{aligned} \dot{P}_b^b &= C_b \frac{\partial V_k(P_b^b)}{\partial P_b^b} + I_6 W_b^b \\ T_b^{b,0} &= I_6 \frac{\partial V_k(P_b^b)}{\partial P_b^b} \end{aligned} \quad (2.31)$$

The kinetic energy function is given as  $V_k = \frac{1}{2} (P_b^b)^T M_b^{-1} P_b^b$ . In cooperative manipulation we often deal with heavy objects, it is thus inevitable to model gravity of the virtual object. A potential energy is assigned to a body in the gravitational field. This can be modelled with a spring connecting the body and an inertial frame associated with the ground. This spring can be formulated as a pHS using the left translation (2.2.1)

$$\begin{aligned} \dot{H}_b^0 &= H_b^0 T_b^{b,0} \\ W_b^{b,0} &= (H_b^0)^T \frac{\partial V_g}{\partial H_b^0} \end{aligned} \quad (2.32)$$

Where  $V_g$  is the gravitational potential energy of the body. For a combined description the potential and kinetic energy add up:  $V_{kg} = V_k + V_g$ . Since there are two types of energy stored by *one* body, the twists in both energy systems are equal. The wrenches on the body add up

$$W_{kg}^b = W_b^b + C_b \frac{\partial V_{kg}}{\partial P_b^b} - (H_b^0)^T \frac{\partial V_{kg}}{\partial H_b^0}$$

Note that the negative sign in the upper equation comes from  $W_b^b = -W_b^{b,0}$ . With this knowledge we can write the combined PHS representation

$$\begin{aligned} \begin{pmatrix} \dot{H}_b^0 \\ \dot{P}_b^b \end{pmatrix} &= \begin{pmatrix} 0 & H_b^0 \\ -(H_b^0)^T & C_b \end{pmatrix} \begin{pmatrix} \frac{\partial V_{kg}}{\partial H_b^0} \\ \frac{\partial V_{kg}}{\partial P_b^b} \end{pmatrix} + \begin{pmatrix} 0 \\ W_{ext}^b \end{pmatrix} \\ T_b^0 &= \begin{pmatrix} 0 & Ad_{H_b^0} \end{pmatrix} \begin{pmatrix} \frac{\partial V_{kg}}{\partial H_b^0} \\ \frac{\partial V_{kg}}{\partial P_b^b} \end{pmatrix} \end{aligned} \quad (2.33)$$

### Dampers

Dampers do not have a state since they do not store energy, they only dissipate it. Note that energy is not "destroyed" in the dampers but transformed into thermal energy. This can be modelled with a thermal port connected to the environment, since we are only interested in free mechanical energy this port is omitted. The easiest way to achieve damping is a linear resistive element  $R$ , such that the wrench is directly proportional to twist. Consider for example a body's motion with respect to the inertial frame

$$W_b^b = RT_b^{b,0} \quad (2.34)$$

Or a damper in parallel with spring

$$W_i^{j,j} = RT_i^j \quad (2.35)$$

The dissipated co-energy is  $E_d = \frac{1}{2}T^T RT$ .

## 2.3 Spring-mass-damper systems

Recall the motivating example from Section 2.1 of a simple spring-mass system. We can add a damper  $d$  to the pHS representation and rewrite eq. (2.5)

$$\begin{pmatrix} \dot{q} \\ \dot{p} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & -d \end{pmatrix} \begin{pmatrix} \frac{\partial V}{\partial q}(q, p) \\ \frac{\partial V}{\partial p}(q, p) \end{pmatrix} + \begin{pmatrix} 0 \\ 1 \end{pmatrix} F_e \quad (2.36)$$

Clearly  $\dot{p} = -\frac{\partial V}{\partial q}(q, p) - d\frac{\partial V}{\partial p}(q, p) + F_e$  equals the mechanical impedance relation  $m\ddot{x} + d\dot{x} + kx = F_e$ . Thus we have a port-Hamiltonian representation of the

impedance control scheme. This is the basis for the control architecture presented in the next chapter. Therefore the mass-spring-damper system, given as a one-dimensional example, is formulated in the  $SE(3)$ . We start from eqs. (2.31,2.32) and add another spring to the body associated with  $\Psi_b$ . This spring connects to a desired object position assigned to  $\Psi_v$ . Its pHs representation is given by

$$\begin{aligned}\dot{H}_b^v &= H_b^v T_b^{b,v} \\ W_b^{b,v} &= (H_b^v)^T \frac{\partial V_s}{\partial H_b^v}\end{aligned}\quad (2.37)$$

The spring's deformation twist is decomposed by  $T_b^{b,v} = T_b^{b,0} - T_v^{b,0}$ . The damping along this spring is  $W_b^b = D_b T_b^{b,v}$ . Body, spring and damper move uniformly with the twist  $T_b^{b,0}$  and the wrenches add up. Combing all components we arrive at

$$\begin{pmatrix} \dot{H}_b^0 \\ \dot{H}_b^v \\ \dot{P}_b^b \end{pmatrix} = \begin{pmatrix} 0 & 0 & H_b^0 \\ 0 & 0 & H_b^v \\ -(H_b^0)^T & -(H_b^v)^T & C_b - D_b \end{pmatrix} \begin{pmatrix} \frac{\partial V_{kg}}{\partial H_b^0} \\ \frac{\partial V_{kg}}{\partial H_b^v} \\ \frac{\partial V_{kg}}{\partial P_b^b} \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ 0 & -H_b^v Ad_{H_b^0} & 0 \\ 0 & D_b Ad_{H_b^0} & I_6 \end{pmatrix} \begin{pmatrix} 0 \\ T_v^0 \\ W_b^b \end{pmatrix} \quad (2.38)$$

## 2.4 Imposing constraints

Many mechanical systems cannot be modelled by a interconnection of springs and masses, already the rigid coupling of two masses restricts their possible motion and has to be treated with constraints. Let us consider this simple example of two masses  $m_1, m_2$  rigidly connected with distance  $c$ . The configuration coordinates are thus  $q_1 = q_2 + c$ . The unconstrained pHs is given according to equation (2.1)

$$\begin{aligned}\begin{pmatrix} \dot{q}_1 \\ \dot{q}_2 \end{pmatrix} &= \begin{pmatrix} \frac{\partial V}{\partial p_1} \\ \frac{\partial V}{\partial p_2} \end{pmatrix} \\ \begin{pmatrix} \dot{p}_1 \\ \dot{p}_2 \end{pmatrix} &= - \begin{pmatrix} \frac{\partial V}{\partial q_1} \\ \frac{\partial V}{\partial q_2} \end{pmatrix} + \begin{pmatrix} g_1(q) & 0 \\ 0 & g_2(q) \end{pmatrix} \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}\end{aligned}$$

The configuration coordinates are thus  $q_1 = q_2 + c$ , time derivation gives  $\dot{q}_1 = \dot{q}_2$ . This *kinematic* constraint can be written with respect to the pHs-formulation

$$0 = \frac{\partial V}{\partial p_1} - \frac{\partial V}{\partial p_2} = \underbrace{(1 \ -1)}_{A(q)^T} \begin{pmatrix} \frac{\partial V}{\partial p_1} \\ \frac{\partial V}{\partial p_2} \end{pmatrix}$$

The interaction forces that arise due to the constraints can be described using the *Lagrange* multiplier  $\lambda$  (see [vdS13] for details). The general representation of con-

strained pHs is thus given by

$$\begin{aligned}
 \dot{q} &= \frac{\partial V}{\partial p} \\
 \dot{p} &= -\frac{\partial V}{\partial q} + A(q)\lambda + g(q)f \\
 e &= g(q)^T \frac{\partial V}{\partial p} \\
 0 &= A^T(q) \frac{\partial V}{\partial p}
 \end{aligned} \tag{2.39}$$

This description is a mixed set of differential and algebraic equations (DAE). The algebraic constraints can be solved and the Lagrange multiplier be eliminated by multiplying equation (2.39) with a suitable matrix  $S(q)$  subject to  $A^T(q)S(q) = 0$ . Therefore  $S(q)$  can be chosen to be the *kernel* of  $A^T(q)$ :  $S(q) = \ker A^T$ . The resulting equation is

$$S^T(q)\dot{p} = -S^T(q)\frac{\partial V}{\partial q} + S^T(q)g(q)f$$

Following [vdS13] we can introduce a coordinate transformation

$$p \mapsto \bar{p} : \bar{p} = S^T(q)p \tag{2.40}$$

The transformed equation is obtained as

$$\dot{\bar{p}} = -S^T(q)\frac{\partial \bar{V}}{\partial q} - p^T[S_i, S_j]_{i,j}\frac{\partial \bar{V}}{\partial \bar{p}} + \bar{g}(q)f$$

Where the Hamiltonian  $\bar{V} = \frac{1}{2}\bar{p}^T\bar{M}^{-1}(q)\bar{p}$  is also expressed in transformed coordinates, the same is done with the input matrix  $\bar{g}(q)$ .  $[S_i, S_j]$  is the *Lie bracket* of the  $i$  and  $j$ -th column of  $S$ :

$$[S_i, S_j] = \frac{\partial S_j}{\partial q}S_i - \frac{\partial S_i}{\partial q}S_j$$

The output equation finally becomes

$$\bar{e} = \bar{g}^T(q)\frac{\partial \bar{V}}{\partial \bar{p}}$$

### Constraints on rigid bodies

Consider a group of rigidly connected bodies, in the center of the group the *virtual object* associated with the coordinate frame  $\Psi_v$ . The bodies surrounding it share the same orientation and the position of the  $i$ -th body is

$$p_i^0 = p_v^0 + R_v^0 p_i^v$$

By differentiating the *geometric* constraints we obtain the *kinematic* constraints

$$\dot{p}_i^0 = \dot{p}_v^0 + \omega_v \times p_i^v$$

$$\omega_i = \omega_v$$

We can reformulate these equations in matrix vector notation and  $i = 1 \dots N$

$$\underbrace{\begin{pmatrix} -I_3 & 0_3 & I_3 & 0_3 & \cdots & 0_3 & 0_3 \\ \tilde{p}_1^v & -I_3 & 0_3 & I_3 & \cdots & 0_3 & 0_3 \\ \vdots & \vdots & & & \ddots & & \\ -I_3 & 0_3 & & & & I_3 & I_3 \\ \tilde{p}_N^v & -I_3 & & & & 0_3 & I_3 \end{pmatrix}}_{A^T(q)} \underbrace{\begin{pmatrix} \omega_v \\ \dot{p}_v^0 \\ \omega_1 \\ \dot{p}_1^0 \\ \vdots \\ \omega_N \\ \dot{p}_N^0 \end{pmatrix}}_{\dot{q}} = 0 \quad (2.41)$$

In order to eliminate the constraint forces from equation (2.39) we require the *kernel* of  $A^T(q)$ , given by

$$S(q) = \ker A^T = \begin{pmatrix} I_3 & 0_3 \\ 0_3 & I_3 \\ I_3 & 0_3 \\ -\tilde{p}_1^v & I_3 \\ \vdots & \vdots \\ I_3 & 0_3 \\ -\tilde{p}_N^v & I_3 \end{pmatrix}$$

This allows to employ the coordinate transformation (2.40) and obtain the constrained momentum. Choosing a representation of the form  $\bar{p} = \bar{M}\dot{q}$  is advantageous when deriving the transformed *Hamiltonian*

$$\bar{p} = \begin{pmatrix} j_v + \sum_{i=1}^N [j_i - m_i(\tilde{p}_i^v)^2] & -\sum_{i=1}^N m_i \tilde{p}_i^v \\ \sum_{i=1}^N m_i \tilde{p}_i^v & m_v + \sum_{i=1}^N m_i \end{pmatrix} \begin{pmatrix} \omega_v \\ \dot{p}_v^0 \end{pmatrix}$$

Note that  $\bar{M}$  is symmetric, this is due to the skew-symmetry of  $\tilde{p}_i^v$ . Thus the *Hamiltonian* is obtained as usual by  $\bar{V} = \frac{1}{2}\bar{p}^T \bar{M}^{-1}\bar{p}$ . One can compute that  $\frac{\partial S_i}{\partial q} = 0 \forall i = 1 \dots N$ , thus the *Lie bracket*  $[S_i, S_j]$  equals zero.

The external wrenches acting on the free bodies sum up for the constrained system, respecting the geometric requirements we obtain

$$\bar{g} = \begin{pmatrix} I_3 & 0_3 & I_3 & \tilde{p}_1^v & \cdots & I_3 & \tilde{p}_N^v \\ 0_3 & I_3 & 0_3 & I_3 & \cdots & 0_3 & I_3 \end{pmatrix}$$

Towards the port-Hamiltonian representation of the constrained system we seek to replace the term  $\frac{\partial \bar{V}}{\partial q}$  by  $\frac{\partial \bar{V}}{\partial \bar{p}}$ . The kinetic co-energy of the system is  $\bar{V}^* = \frac{1}{2}\dot{q}^T \bar{M}\dot{q}$ .

## Chapter 3

# Control of port-Hamiltonian systems

### 3.1 The Intrinsically Passive Controller (IPC)

The IPC is a control architecture based entirely on physical intuition. The structure can be seen in Fig. 3.1, it is exclusively a geometric interconnection of springs, inertias and dampers. The manipulators are connected with spatial springs to the object. The object is modelled by a virtual inertia and its shape is represented by a sphere that does not necessarily coincide with the actual shape. The resulting virtual object is subjected to forces exerted by the manipulator springs and is connected to the environment with another spatial spring. Note that these springs do not exist in reality, they are models to establish compliant behaviour in the controller domain. The simulated manipulator forces are then applied to the real object, in order to transfer the virtual compliant behaviour to the real world.

Starting point for the controller design is the virtual object. It is already given by equation (2.38). Springs to environment and manipulators exert wrenches on the object, in terms of port-Hamiltonian representation they are connected through the control port. The inertias of the manipulators should be equal to their real equivalents. Inertia re-shaping, using a local feed-back linearising compensation for the robot, can lead to infinite energy supply [Str01b] and would thus violate passivity. In the absence of feed-back linearising the robot exhibits its internal dynamics at the end-effector. Therefore the inertia and Coriolis terms of the manipulators are configuration dependent. For the sake of simplicity we will omit this dependency in the following. Moreover we assume the robots to be gravity compensated and use the simpler port-Hamiltonian inertia representation of equation (2.31).

From a geometric point of view the object-environment spring directly connects to the virtual object frame  $\Psi_b$ . The other end is attached to the desired object position, denoted with frame  $\Psi_v$ . This desired object position is the main control objective, by means of this, the motion of the constrained robot-object system is directed. The

Figure 3.1: Structure of the IPC [SMA99]

representation in PHS form is:

$$\dot{H}_v^b = T_v^b H_v^b \quad (3.1)$$

$$W_v^b = \frac{\partial V_{v,b}}{\partial H_v^b} (H_v^b)^T \quad (3.2)$$

Since we already have a spring relation between the virtual object and the inertial frame it is useful to split this spring into two springs: one between desired position and inertial frame and the other between inertial frame and object position:  $H_v^b = H_0^b H_v^0$ .

Additionally we have a spring connecting object and each of the  $n$ -manipulators. As stated before these are variable rest-length springs, to allow for contraction and widening of the formation. Therefore the springs do not connect to the object frame but to a additional supporting frame denoted by  $\Psi_v(i)$ , which is rigidly attached to  $\Psi_b$ . Clearly the frames  $\Psi_v(i)$ ,  $i = 1 \dots N$  define the sphere of the virtual object. The springs are situated between the manipulators and the virtual object sphere:  $H_{v(i)}^i$ . The rest-length is between the sphere and the virtual object frame:  $H_b^{v(i)}$ , the set-up is illustrated in Fig. 3.2.

### Geometric interconnection of springs

To combine all the presented equations to the full system as shown in Fig. 3.1, we express the spring equations with respect to the inertial frame  $\Psi_0$ . This is done for

Figure 3.2: Virtual object and springs [WOH08]

the virtual object spring by splitting the twists

$$T_b^v = \begin{pmatrix} Ad_{H_0^v} & -Ad_{H_0^v} \end{pmatrix} \begin{pmatrix} T_b^0 \\ T_v^0 \end{pmatrix}$$

and the wrenches which obey the principle of action and reaction.

$$\begin{pmatrix} W_b^0 \\ W_v^0 \end{pmatrix} = \begin{pmatrix} Ad_{H_0^v}^T \\ -Ad_{H_0^v}^T \end{pmatrix} W_b^v$$

We can write the resulting PHS using the left translation (2.2.1)

$$\dot{H}_b^v = H_b^v \left( \begin{pmatrix} Ad_{H_0^b} & -Ad_{H_0^b} \end{pmatrix} \begin{pmatrix} T_b^0 \\ T_v^0 \end{pmatrix} \right) \quad (3.3)$$

$$\begin{pmatrix} W_b^0 \\ W_v^0 \end{pmatrix} = (H_b^v)^T \left( \begin{pmatrix} Ad_{H_0^b}^T \\ -Ad_{H_0^b}^T \end{pmatrix} \frac{\partial V_{v,b}}{\partial H_b^v} \right) \quad (3.4)$$

This is done with the springs connecting the  $i$ -th manipulator to the virtual object sphere in the same manner:  $T_{v(i)}^i = Ad_{H_0^i} T_b^0 - Ad_{H_0^i} T_i^0 + Ad_{H_i^i} T_{v(i)}^b$ . Note that the twists and wrenches of rest-length changes are not expressed w.r.t. the inertial frame, since they represent a distinct power port. The resulting PHS for the spring

connecting the  $i$ -th manipulator to the virtual object using the left translation is

$$\dot{H}_{v(i)}^i = H_{v(i)}^i \left( \begin{pmatrix} Ad_{H_0^{v(i)}} & -Ad_{H_0^{v(i)}} & Ad_{H_b^{v(i)}} \end{pmatrix} \begin{pmatrix} T_b^0 \\ T_i^0 \\ T_{v(i)}^b \end{pmatrix} \right) \quad (3.5)$$

$$\begin{pmatrix} W_b^0 \\ W_i^0 \\ W_{v(i)}^b \end{pmatrix} = (H_{v(i)}^i)^T \left( \begin{pmatrix} Ad_{H_0^{v(i)}}^T \\ -Ad_{H_0^{v(i)}}^T \\ Ad_{H_b^{v(i)}}^T \end{pmatrix} \frac{\partial V_{v(i),i}}{\partial H_{v(i)}^i} \right) \quad (3.6)$$

For a simpler presentation we collect the twists and wrenches of the  $n$  manipulator springs in a stacked vector notation

$$T_i = \begin{pmatrix} T_1^0 \\ \vdots \\ T_N^0 \end{pmatrix}, \quad T_{rl} = \begin{pmatrix} T_{v(1)}^b \\ \vdots \\ T_{v(N)}^b \end{pmatrix}, \quad W_i = \begin{pmatrix} W_1^0 \\ \vdots \\ W_N^0 \end{pmatrix}, \quad W_{rl} = \begin{pmatrix} W_{v(1)}^b \\ \vdots \\ W_{v(N)}^b \end{pmatrix}$$

As a result we can combine all springs in a PHS

$$\underbrace{\begin{pmatrix} \dot{H}_{v(1)}^1 \\ \vdots \\ \dot{H}_{v(N)}^N \\ \dot{H}_b^v \end{pmatrix}}_{\dot{x}_s} = (\phi_b \quad \phi_v \quad \phi_i \quad \phi_{rl}) \begin{pmatrix} T_b^0 \\ T_v^0 \\ T_i \\ T_{rl} \end{pmatrix} \quad (3.7)$$

$$\begin{pmatrix} W_b^0 \\ W_v^0 \\ W_i \\ W_{rl} \end{pmatrix} = \begin{pmatrix} \phi_b^T \\ \phi_v^T \\ \phi_i^T \\ \phi_{rl}^T \end{pmatrix} \frac{\partial V_s}{\partial x_s} \quad (3.8)$$

Where  $V_s = V_{v,b} + \sum_{i=1}^N V_{v(i),i}$  is the sum of energy stored in the springs. The geometric interconnection of the springs is described by the matrices  $\phi_b, \phi_v, \phi_i, \phi_{rl}$ , their structure can be easily derived from the previous equations where every spring is described

$$\phi_b = \begin{pmatrix} H_{v(1)}^1 Ad_{H_0^{v(1)}} \\ \vdots \\ H_{v(N)}^N Ad_{H_0^{v(N)}} \\ H_b^v Ad_{H_0^b} \end{pmatrix}, \quad \phi_v = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ -H_b^v Ad_{H_0^b} \end{pmatrix},$$

$$\phi_i = \begin{pmatrix} -H_{v(1)}^1 Ad_{H_0^{v(1)}} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & -H_{v(N)}^N Ad_{H_0^{v(N)}} \\ 0 & \cdots & 0 \end{pmatrix}$$

$$\phi_{rl} = \begin{pmatrix} H_{v(1)}^1 Ad_{H_b^{v(1)}} & \cdots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \cdots & H_{v(N)}^N Ad_{H_b^{v(N)}} \\ 0 & \cdots & 0 \end{pmatrix}$$

### Interconnection of springs and inertias

Having obtained a complete geometric description of the springs we can now add the inertias. The virtual object is attached to both, the environment spring and the manipulator springs. In the simulation the external forces acting on the inertia exclusively originate from these springs, thus  $W_{ext}^b = -Ad_{H_b^0}^T W_b^0$ . The wrench acting on the  $i$ -th manipulator stems from the  $i$ -th manipulator spring but also from the real manipulators:  $W_{ext}^i = -Ad_{H_i^0}^T W_i^0 + Ad_{H_i^0}^T W_{m(i)}^0$ . Along with its dual twist we obtain the port that connects to the real robotic system, i.e. the robot control port. Concerning the twists we derive from equation (2.38) that  $T_b^0 = Ad_{H_b^0} \frac{\partial V_{kg}}{\partial P_b^b}$ .

Equivalently the  $i$ -th manipulator wrench can be expressed as  $T_i^0 = Ad_{H_i^0} \frac{\partial V_{k,i}}{\partial P_i^i}$ . With this knowledge we can write the PHS representation of the complete control model. In order to keep the formulation compact we use the stacked state vector of the object inertia  $x_b = ((H_b^0)^T (P_b^b)^T)^T$ , the stacked vector of the spring states  $x_S$  (defined in eq. (3.7)) and the vector of the manipulator inertia states  $x_M = ((P_1^1)^T \cdots (P_N^N)^T)^T$ . Analogously to the previous we write compactly for the manipulator wrenches  $W_m = ((W_{m(1)}^0)^T \cdots (W_{m(N)}^0)^T)^T$ .

$$\begin{pmatrix} \dot{x}_b \\ \dot{x}_S \\ \dot{x}_M \end{pmatrix} = \begin{pmatrix} J_B & -\phi_B^T & 0 \\ \phi_B & 0 & Ad_{H_i^0} \phi_i \\ 0 & -\phi_i^T Ad_{H_i^0}^T & C_M \end{pmatrix} \begin{pmatrix} \frac{\partial V_c}{\partial x_b} \\ \frac{\partial V_c}{\partial x_S} \\ \frac{\partial V_c}{\partial x_M} \end{pmatrix} + \begin{pmatrix} 0 & 0 & 0 \\ \phi_v & \phi_{rl} & 0 \\ 0 & 0 & Ad_{H_n^0}^T \end{pmatrix} \begin{pmatrix} T_v^0 \\ T_{rl} \\ W_m \end{pmatrix} \quad (3.9)$$

$$\begin{pmatrix} W_v^0 \\ W_{rl} \\ T_i \end{pmatrix} = \begin{pmatrix} 0 & \phi_v^T & 0 \\ 0 & \phi_{rl}^T & 0 \\ 0 & 0 & Ad_{H_n^0} \end{pmatrix} \begin{pmatrix} \frac{\partial V_c}{\partial x_b} \\ \frac{\partial V_c}{\partial x_S} \\ \frac{\partial V_c}{\partial x_M} \end{pmatrix} \quad (3.10)$$

Where  $V_c = V_{v,b} + \sum_{i=1}^N [V_{v(i),i} + V_{k,i}] + V_{kg}$  is the combined energy function.  $J_B$  is given in equation (2.38) and  $C_M$  combines the Coriolis terms of all manipulators. The geometric interconnection matrix  $\phi_B$  is composed by

$$\phi_B = \begin{pmatrix} 0 \\ Ad_{H_b^0} \phi_b \end{pmatrix}$$

The reference inputs are  $T_v$  and  $T_{rl}$ , allowing a high level control to specify twist trajectories for the object and the spring rest-lengths. Force-feedback is provided by their dual quantities. The robot system is connected with the port  $(W_m, T_i)$ ,  $W_m$  being the input and  $T_i$  the output. Usually a robotic system expects the wrench to

be the reference input and provides the resulting twist information. The concept of port-Hamiltonian systems allows for a simple inversion of causality by using a *gyrator*. The power conserving relation is

$$\bar{W}_m = -T_i$$

$$\bar{T}_i = W_m$$

The system is lossless, since no damping terms have been added so far.

### Adding damping

The motion of the virtual object is damped with respect to the inertial frame  $\Psi_0$ . The object twist is already given in equation (2.38) and the generates the damping wrench in object as defined in Subsection 2.2.2. The resulting PHS representation of the virtual damped object is

$$\begin{pmatrix} \dot{H}_b^0 \\ \dot{P}_b^b \end{pmatrix} = \underbrace{\begin{pmatrix} 0 & H_b^0 \\ -(H_b^0)^T & C_b - R_b \end{pmatrix}}_{J_B - R_B} \begin{pmatrix} \frac{\partial V_{kg}}{\partial H_b^0} \\ \frac{\partial V_{kg}}{\partial P_b^b} \end{pmatrix} + \begin{pmatrix} 0 \\ W_{ext}^b \end{pmatrix}$$

$$T_b^0 = \begin{pmatrix} 0 & Ad_{H_b^0} \end{pmatrix} \begin{pmatrix} \frac{\partial V_{kg}}{\partial H_b^0} \\ \frac{\partial V_{kg}}{\partial P_b^b} \end{pmatrix}$$

Damping for the manipulators shall be performed along the springs connecting the manipulator to the object. Recall that the twist of the  $i$ -th spring is

$$T_{v(i)}^i = Ad_{H_0^i} T_b^0 - Ad_{H_0^i} T_i^0 + Ad_{H_b^i} T_{v(i)}^b$$

The first component  $T_b^0$  is already covered by the damping of the virtual object. The last component  $T_{v(i)}^b$  is commanded by the operator and is executed unchanged. The remaining component  $T_i^0$  relates to the motion of the manipulator inertia. Rewriting equation (2.31) we can give the damped manipulator inertia in PHS form

$$\dot{P}_i^i = (C_{m(i)} - R_i) \frac{\partial V_{k,i}(P_i^i)}{\partial P_i^i} + I_6 W_{ext}^i$$

$$T_i^{i,0} = I_6 \frac{\partial V_{k,i}(P_i^i)}{\partial P_i^i}$$

It is easy to seen how the damping integrates into the complete system representation, therefore it will not be given here again.

## 3.2 Performance Comparison of control strategies

To evaluate the presented controllers in an objective way, they are implemented in *Simulink* and compared in terms of:

- Trajectory tracking
- Dynamic behaviour
- Internal Forces

### 3.2.1 Internal impedance control with feed-forward of the object dynamics

De Pascali et al. [DPEZ<sup>+</sup>15] present combination of impedance control on manipulator/object level and feed-forward object dynamics. The internal impedance control relation (between object and manipulator) encompasses a spring and a parallel damper, inertia is used to feed-forward the desired acceleration:

$$M_i \ddot{x}_i^d + D_i(\dot{x}_i^d - \dot{x}_i) + K_i(x_i^d, x_i) = h^x \quad (3.11)$$

*I know I have to use consistent notation and explain the variables, comes later ;)*  
This avoids the necessity of either measuring manipulator acceleration or contact force. Object dynamics is represented with a feed-forward term, mapped to the manipulators with a weighted pseudoinverse  $G^+$  of the grasp matrix:

$$h^d = G^+(M_o \ddot{x}_o^d + C_o \dot{x}_o^d + g_o) \quad (3.12)$$

Note that this term is not an impedance relation and does not adjust if the environment hinders motion. The combined control law is  $h^\Sigma = h^x + h^d$ .

The set-up consists of four manipulators, distributed symmetrically around the object. In the first case translation in x-direction commanded. Results in Fig. 3.3 show good tracking behaviour: no position errors in steady state and only small deviations from the desired values during transient phase. No internal stress is exerted on the object. Due to fast translation high manipulator forces occur.

In the second test case the object is rotated around the z-axis. This is done at a significantly lower speed of at most 1 rad/s, thus the manipulator forces are smaller, desired and actual object trajectory cannot be distinguished in Fig. 3.4. However some small internal forces can be seen. Interestingly they are proportional to the simulation step size (running *Simulink's ode3* solver), i.e. a ten-times smaller step size gives ten-times smaller internal forces. Internal forces are calculated based on the geometry in the last simulation step. The correlation between step size and values indicates that these forces are rather due to the discrete nature of the simulation than of the control law generating internal stress. Simulation of the constrained system dynamics as well as calculation of internal wrench is done as described in [EH15].

### 3.2.2 Internal and external impedance based reference trajectory generation

Caccavale and Villani [CV01] combine both internal and external impedance control. With external we mean a compliant relation between object and (external) environment. The architecture is cascaded, consisting of a two level reference trajectory generation and a motion control loop below. On top-level an impedance relation between object and environment is used to generate a compliant trajectory subject to environmental forces:

$$\alpha M_o(\ddot{x}_o^d - \ddot{x}_o^r) + D_o(\dot{x}_o^d - \dot{x}_o^r) + K_o(x_o^d, x_o^r) = h_{env} \quad (3.13)$$

The constant  $\alpha$  scales the object inertia proportionally to a desired value. The control output is the reference object acceleration  $\ddot{x}_o^r$ ,  $h_{env}$  is an input. This is sometimes called admittance control, admittance being the inverse of impedance.  $h_{env}$  has to be known, but is not easily measured in a practical set-up. Recalling (??) the environmental forces can be expressed as:

$$h_{env} = M_o\ddot{x}_o^r + C_o\dot{x}_o^r + g_o - G^\dagger h \quad (3.14)$$

Herein  $G^\dagger$  is a generalized inverse of the grasp matrix, selecting the motion inducing components from the measured contact wrench  $h$ .  $\dot{x}_o^r, x_o^r$  are calculated from  $\ddot{x}_o^r$  by integration. From the compliant object trajectory  $(\ddot{x}_o^r, \dot{x}_o^r, x_o^r)$  the desired trajectories of the manipulator  $(\ddot{x}_i^d, \dot{x}_i^d, x_i^d)$  using the kinematic constraints. The reference manipulator trajectory, enforcing compliant behaviour between manipulators and object, is calculated from manipulator dynamics and internal forces:

$$M_i(\ddot{x}_i^d - \ddot{x}_i^r) + D_i(\dot{x}_i^d - \dot{x}_i^r) + K_i(x_i^d, x_i^r) = VV^\dagger h \quad (3.15)$$

The control output is the reference acceleration of the  $i$ -th manipulator  $\ddot{x}_i^r$ ,  $\dot{x}_i^r, x_i^r$  are obtained from integration. These variables are the inputs the inner motion control loop (PD-type). The strategy of compliant trajectories allows for high gains in the motion controller. Knowledge of object dynamics and measurement of the contact wrenches is required.

Results for translational motion (see Fig. 3.5) are very similar to that of the previous control scheme.

When it comes to rotation, higher internal forces can be observed in Fig. 3.6. In this case they are not influenced by numerical parameters of the simulation.

This architecture in contrast to the previous makes use of measured contact wrenches. Contact wrench as measured can be obtained from the constrained system simulation. As described in [CM08] this wrench is then decomposed by kineostatic filters in internal and external components. In this simulation this not cancel out undesired internal stress but magnifies it: when the contact wrench is not fed back and set to zero in the internal force impedance controller, results are slightly better. Note that the simulation represents an ideal case, where all parameters are exactly known

and no deviations in grasp positions occur. Behavior in a real experiment may be different and this observation does not mean that the kineostatic-filtered feed-back of contact wrench is unjustified in general.

### 3.2.3 Intrinsically Passive Controller (IPC)

Introduced by Stramigioli [Str01b] and implemented by Wimböck et al. [WOH08], the architecture has been detailed throughout this work. In contrast to Stramigioli dampers are used in parallel with the manipulator springs and in contrast to Wimböck all springs have 6-DoF. Simulation results for pure translation can be seen in Fig. 3.7. The object trajectory falls slightly behind the reference input, the dynamic behaviour is inferior to the previous approaches. Despite very stiff springs the magnitude of force seen in the previous approaches is not reached. No internal forces can be observed.

When it comes to rotation (see Fig. 3.8) again the dynamic behaviour falls short of the two other approaches, while the manipulator wrench is higher. Significant internal wrenches are present, they amount up to 50% of the manipulator wrenches.
